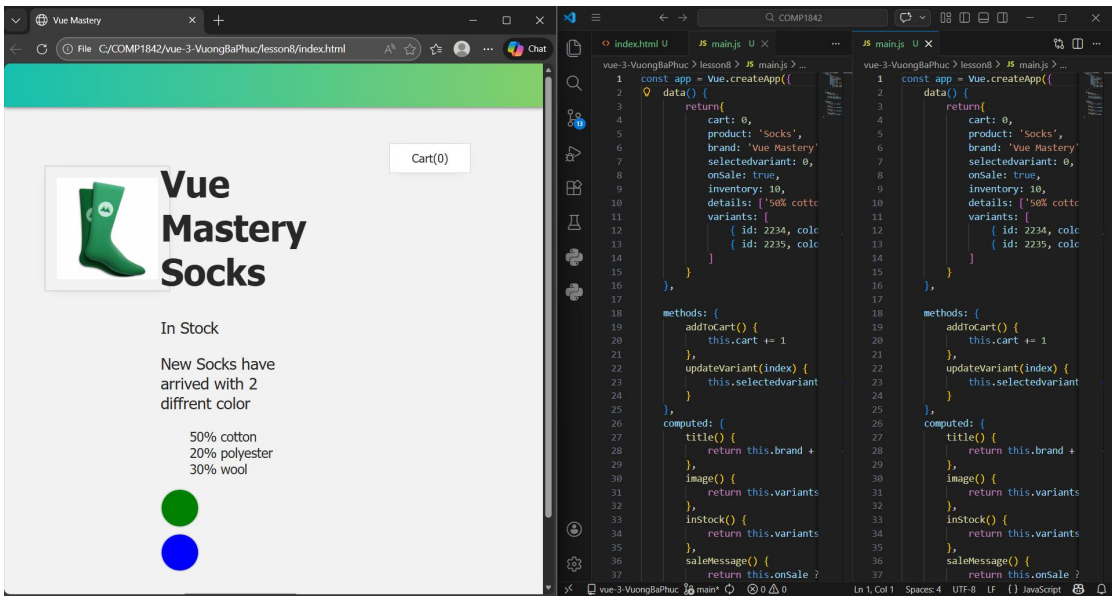
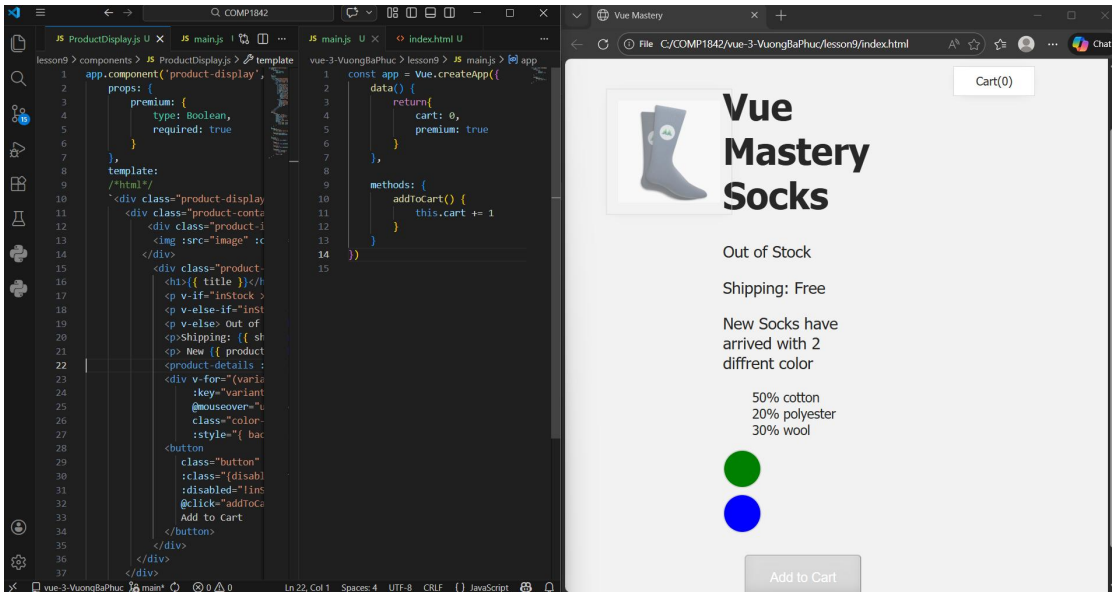
Vue3

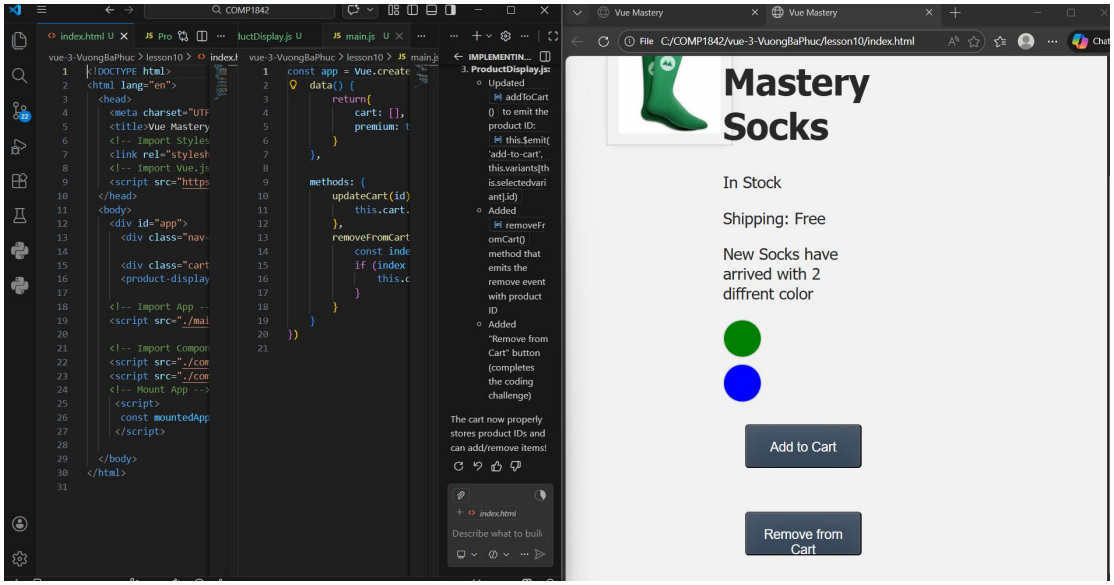
Lesson 8



Lesson 9



Lesson 10



Understanding

Lessons 8–10 extend the understanding of Vue 3 from basic reactivity into component structure, data flow, and real-world application organization. Lesson 8 introduces components as the core building blocks of a Vue application. Instead of managing the entire UI in a single file, components allow the interface to be broken into smaller, reusable, and self-contained pieces. This encourages better separation of concerns, improves readability, and makes applications easier to scale and maintain. Understanding components also clarifies how templates, data, and logic are encapsulated within each unit.

Lesson 9 focuses on communication between components, particularly through props. Props enable parent components to pass data down to child components in a controlled and predictable way. This reinforces Vue's one-way data flow model, where data moves downward while events are emitted upward. By following this pattern, applications become easier to reason about, as changes in state can be traced clearly. This lesson highlights the importance of treating props as read-only and using them purely for presentation and configuration.

Lesson 10 deepens this understanding by introducing events and user interaction across components. Emitting events allows child components to notify parents about user actions without directly modifying parent data. Together, props and events form a clean communication contract. Overall, Lessons 8–10 emphasize structured design, predictable data flow, and loose coupling between components, which are essential for building maintainable, testable, and professional Vue applications.
